MEETING

TO:

Distribution List

FROM:

L. G. Roberts

SUBJ:

Coral List Structure System; Introduction and Examples

SPEAKER:

L. G. Roberts

TIME:

1:00 - 3:00, Thursday, July 23rd.

ROOM:

A-258

Coral is a list structure language for the TX-2 which allows the user to create, associate, and delete variable length list structure blocks. The language is a set of M4 macro commands. In order to familiarize potential Coral users with the use of the macros a series of example problems will be examined.

This meeting will be the first of a series on Coral. The more sophisticated macros such as the class macros, will be discussed at a later time. However, concepts basic to their understanding will be discussed.

31 July 1964

TO: TX-2 Distribution List

FROM: L. G. Roberts

SUBJ: CORAL Meeting

This session for CORAL users will involve a short review, many examples and an introduction to the class concepts.

SPEAKER: L. G. Roberts

DATE: Monday, 3 August 1964

TIME: 1:00 - 3:00 p.m.

PLACE: A-258

MASSACHUSETTS INSTITUTE OF TECHNOLOGY Lincoln Laboratory

28 May 1964

TO: Users of Class Oriented Ring Associative Language (CORAL)

FROM: Larry, Alex

REF: Charts for Blockheads, NUBs, and Ring Macros

Charts for Blockheads and NUBs are attached and briefly explained below. A tabulation of available Ring Macros is also included and will be explained later.

Rlockheads

There are now several types of blocks (2¹⁷-1). Complete format details will be kept in a "Master Block" for each. The Flockhead gives fairly complete format information for some; less for others depending on the kind (type) of block. The type-numbering scheme includes all varieties: Blocks, Nubs, Quads etc. (Even Triads and Tubs if they are allowed to exist.)

When you ask the blockmaker macro for a block, you must specify the Type Number desired. The master block determines the number of ties. Where ever "i" appears in the blockhead you can specify a data length that differs from the master spec. In all other cases, the master rules. "ii" is included in the Blockhead to tell where the data is without a master block reference.

Nubs etc.

The word "Nub" is now a class name. Where "nub" was used heretofore, we now use "plain nub" if such precision is required. There are 8 varieties of Nubs and two kinds of QUADS (Quad 4 and Quad 3). A Quad is a 4 register block with a Ring Start (Hen) on top (No Blockhead). A quad 4 is 4 tie registers. A quad 3 has 3 tie registers and a data register (which must come last). A quad may look like two nubs, but its real ancestor is the "BLOCK". Except for the top Hen, its tie registers have 2.9 = 0 and the data word of a Quad 3 is a full 36 bits.

Ring Macros

The attached list gives the "Macro" and "English" names for the current set of Standard Ring Macros. There is a growing amount of stability surrounding this list - people are using them. Detailed verbal descriptions of each ring macro will be prepared soon.

A. Vanderburgh

NOD CHAILS				
Format	Name	Diagram	Number	Type Number Range
0 -1 1	Hub (See Note 9)	\$	1000	360000 - 360777
0 -1 3	T stub	(P)	1000	361000 - 361777
1 2	Y stub	3	1000	362000 - 362777
	Nub		1000	363000 - 363777
0 -0 A	Hub Item	(a state of the s	1000	364000 - 364777
0 4 - b	T stub Item		1000	365000 - 365777
1 -0 A	STUD	Pata	1000	366000 - 366777
	DUB	Data	1000	367000 - 367777

Notes:

- 1. Except for "full" data words in DUBS and STUDs, 2.9 must be 1.
- 2. If quarter 4 is -0 or -1, the tie register is a Ring Start (HEN).
- 3. As in HUB and T STIB ITEMS might be interpreted as the right half of a type number by some people someday.
- 4. " in diagrams is a Ring Start (HEN).
- 5. (straight thum) is a (weep sob!) chicken.
- 6. Data
- 7. The left half of a chicken is either a back or hen tie.
- 8. STUDs and DUBs are now upside down data is on top.
- 9. The two mine bit data words of a Hub are not available to ordinary Users.

Kind of Block	Blockhead Format*	Block Use	Number of blocks	Range of type Nbrs.
1.	DRFT	Normal,	200,000	0 - 177,777
20	LE VOLT	Fixed Data Length	100,000	200,000 - 277,777
3.	(ZYWY F)	Variable Data "	40,000	300,000 - 337,777
4.	L. L. I.	Length 256 _d (page)	20,000	340,000 - 357,777
5.	NUBS	atter and a confidential expension of a star directiveness and a substitution of the	10,000	360,000 - 367,777
6.	Not Used	general El Tractico de Companyo (no esta companyo en esta companyo en esta companyo esta companyo esta company	4,000	370,000 - 373,777
7. a.)	[-//Feb	Quad 4	1,000	374,000 - 374,777
b.)	(4)	Quad 3	1,000	375,000 - 375,777
8.	2/// =	Fixed. Last 100 reserved.	1,777	376,000 - 377,677
				376,700 - 377,776

*Notes:

1. My = Number of Tie Registers +1

A = Total Lenght of Block.

T = Type Number

T = Right half of type number.

2 = Data

- 2. All Blocks, NUES, and QUADS are located in memory starting at an Even numbered register.
- 3. Diagrams for Quads are generally one of the following:

The diagram below is the Ring Structure Created by Larry's sample program if you type:

YOU WILL LIKE CORAL IF YOU USE CORAL

6 1000

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

LINCOLN LABORATORY

TO:

All Ranchhands and APEX Workers 17 July 1964

FROM:

Larynx (Larry & Alx)

RE:

CORAL - Class Oriented Ring Associative Language

(Formally known as Larry and Bert's RING MACROS)

FORWARD:

CORAL is a set of M4 Macro-instructions designed for the creation of data files as ring-structured tables and for data manipulation through flexible arrangement and variation of "ties" or "pointers." It is especially applicable to cases where there will be considerable categorization and recombination of data and where one set of data is strongly related to another.

For example:

- 1. Electronic Circuit Simulation Graphical, Electrical, and Topological Parameters.
- 2. Programming Language Conversion Flow Diagram, Symbolic Manuscript, Machine Language Code.

The document that follows is an attempt to introduce the jargon and use of CORAL. Neither this memo nor CORAL itself is complete as yet but in the interest of communication and coordination . . .

OUTLINE

- 1. Jargon
- 2. General Format Comments
- 3. Specific Macros
 - A. Move Pointer
 - B. Test
 - C. Data
 - D. A. E.
 - E. Miscellaneous
 - F. Change
 - G. Class Macros
- 4. Examples
- 5. Macro Summary Chart

I. Jargon

Block A group of registers (Block Head) The top register of a Block ("Top" is ("The Top") low numbered end, and is always on even numbered address.) (Pointer) A 17-bit word used to 'Point" at something (Tie of interest. (i.e., it is the address or memory location of the thing it points to.) List A set of blocks tied together with "Pointers" (i.e., Ties) that tell where the next block is. Tie Register A register that contains the "Pointer" or "Tie." Ring . A list tied back to its beginning. Ring Start The first tie register of a Ring. It is Tie Register (Hen) also called a HEN. (RSTR = Rooster = Hen) Quarter 4 is either -0 or -1 for identification. See below: 2.9 marker

> 17 Bit Pointer

A 'Nothing"

-- A "Nothing" is a register that cannot look like a Hen or Chicken. In pure form it contains -0 ,, 0.

Ring Element Tie Register (Chicken)

-- Chicken (sorry -- no justification possible yet) A chicken is the ordinary tie register.

Tie Register Pair -- NUB

-- One of a set of special 2-word blocks -- (See NUB chart)

Item

- A NUB that contains data of some sort.

(See NUB chart)

List Structure

Any set of blocks, rings, Nubs, etc. of this sort, i.e. tied up in rings & things.

Index or (Dictionary)

A List Structure based on a string of character codes where one works through the structure by using each code in turn. i.e., the first letter determines the entry point, the second letter, how far around the first ring, the third, how far down the next ring, and so forth until the end. The data itself or a pointer to it would be found in the last block. (or NUB or ITEM as the case may be)

Class

A group of things you wish to refer to by name. They will commonly be ordered automatically by the ring macros, and the structure will be designed for logarithmic search. Note all nubs of a given structure will have the same type number.

Free Ring (or Free List)

All available storage is tied together in as few blocks as possible on the "FREE" ring,

Pointer Register A tagged register containing a pointer but outside any ring structure. Its pointer probably points AT some particular structure entry point. Its TAG might be thought of as the name for the whole structure.

Back Pointer

A pointer in the left half of a CHICKEN TIE

REGISTER that points to the closest previous

(left) chicken that also has a Back Pointer.

(See also HEN POINTER.)

Ring Start
Pointer
(Hen Pointer)

A pointer in the left half of a CHICKEN TIE
REGISTER that points to the HEN (Ring START
TIE REGISTER). Lefthand Pointers alternate
(between BACK and HEN) in a "well formed" or
"undisturbed" ring. This allows rapid access

to the RING START (HEN) without losing access to the previous ring element.

Master Block

For each type number, the system will hold a MASTER BLOCK containing all block format information and perhaps other information if such is needed by the macros.

Type Number

Each element of a given list structure Blocks, NUBS, QUADS, etc. will have a Type
Number. These numbers are to be assigned
from the Blockhead Chart and with the cooperation of other users. A given block
format and MASTER BLOCK can have but one Type
Number (and vice versa). You can, of course,
use as many blocks of the same type as you
need.

MACRO (Macro Instruction)

An abbreviation for a flexible subprogram.

The CORAL language is a coherent set of macros, designed for manipulation of RING STRUCTURES.

(See LM 45, TX-2 Users Handbook, chapter 6, page 6-29).

Macro Definition Macro Name Dummy Parameter

See LM 45, TX-2 Users Handbook, page 6-29.

II. Terminators, Dummy Parameters, and Comments

A. Comments:

- 1.) Use parentheses to nest macros.
- 2.) Undefined parameters will be set to their value in the next nest, or the next, or the next, right back to the main program.
- 3.) The Accumulator is used for inter-macro communication. It usually contains a pointer (in the right half).
- 4.) Pointers will usually point to Tie Registers. Many macros count on this for correct operation. For example, if you are pointing at the Data portion of a block, the macros can not find the blockhead.
- 5.) Entrance to subroutine is usually just an address e.g. "SB". The macro creates JPQ SB. You can embellish it at your whim e.g. h'SB, becomes h BPQSB, 2SB, becomes JES, SB etc. Use index γ for subroutine entrance, and BPQ, o (index χ) for return.
- 6.) The macros use index registers \langle , \rangle , and λ .
- B. Terminators and Dummy Parameters that always mean the same thing:
 - 1. \rightarrow S STA S --- Used to save the current pointer. S may have config. and/or index syllables. Check carefully before using a Macro.
 - 2. FR JPQ R --- Always at the end of the macro. R may have config. and/or index syllables. Check carefully before using a macro.

3. P (at left)

LDA P --- Used as a way to get started. Not used if A already has the desired pointer. (One can often get started by use of a macro instead.)

4. ~ q

 ${\tt q}$ is the desired configuration. If not specified, ${\tt q}=1$ in comparisons and ${\tt q}=0$ in arithmetic.

5. N

N is usually a count. If an honest tag or expression containing such is given, the macro looks in that register for the count. If a macro is given, the generated number is used.

6. TP

TP is usually a TYPE NUMBER although it may be the same as { Type Number}, or a Macro that computes the type number.

III. Individual Macros

MOVE Macros e.g.

PAN→S=R

(Note: There is no protection, you can "move" right out of the block.)

NA	acro ME SYMBOL)	Common Use	English Name and Comment
	4	↑ N	"Move UP" N moves the current Pointer (in A)
			up the manuscript N Places (i.e. toward lower
			numbers). Changes A ₂₁ , C ₂₁ , D ₂₁ and Z ₂ .
,	 	↑ M	"Move DOWN"
	}	≯ N	"MOVE RIGHT" N moves the pointer N elements around
			the ring to the right. This is the preferred
			direction. N can be as large as you wish, it
			just keeps going around. Changes A, 8, 4.
1	k	≮ M	Theorem a respect to the control of
		, M	"MOVE LEFT" N. It takes longer to move to the
			left around a ring, for the Ties alternate and extra
			checking is required. Changes A, γ, α .
7		₹ N	DOWN from the top N places. Starting point must
			be a Tie Register or Blockhead. There is no
			protection: You can move past the end of the block.
			If you use zero for N, you stay at the TOP. Changes
			A, C ₂₁ , D ₂₁ ,α, β, Z ₂ .

Macro NAME (or SYMBOL)	Common Use	English Name and Comment
本	不N	Around the <u>TOP</u> and <u>Up</u> from the bottom N Places. Same comments as above apply. Note that if N is zero or missing, you stay at the top. Changes A, C_{21} , D_{21} , α , γ , Z_{2} .
3	₹ N	Move N places to the right of the hen (Ring Start). If N is zero or missing, you will point to the hen. (Ring Start) Changes A, α , \forall .
₹	₹ N	Move N places to the <u>left</u> of the Ring Start (HEN). (Same comments as above.) Changes A, B, α , γ .
Ē	Ē	FLIP to other side of NUB. Note that this amounts to MKC1.1 A. Changes A21.
D.	D N	Move to $N^{\frac{th}{L}}$ Data register of the block. Be sure to move out of the data portion if you wish to use the macros that must have access to the TOP. Changes α , γ , A, B, C, D.
M	M TP	Move to Master block for type number "TP". You will be pointing at the third register of the Master block. (i.e. at the start of the "Type Ring".)
	P M	If no type number is give, the macro will go to the TOP of the block to find one and then proceed to the master. If it can not find one, e.g. if Block is a nub or special block, then -l is returned as an error

signal.

Macro NAME (or SYMBOL)	Common	English Name and Comment
B	SB SB	Go Round Ring to the right, doing subroutine "SB" for each element. SB can also be a macro expression Macro generates the jump to SB and sets up L for return via BPQ $_\lambda$ o.
	SB∧L	L is the address or name of a push down List provided so that a recursive "go round" can be done conveniently. (See examples) Use JES of to recurse.
3	SB	Go Round Left: Similar to Go Round Right except slower.

B. TEST MACROS

Notes:

- 1. Two arguments are compared. One comes into A via LDA P.
- 2. The other argument is specified by $\ensuremath{\mathsf{Q}}$
 - a) If Q is a number, that number is the second argument.
 - b) If Q is a tag, the contents of Q is the second argument.
 - c) If Q is a macro, its result is the second argument.
- 3. The comparison is made under the aegis of configuration "q". For this group of macros, q = 1 if not specified.
- 4. YES (and/or NO) can be a macro, a Tag, or a Subroutine Entry. A macro is just evaluated as always. A Tag is used as an exit jump-no provision is made for return.

lacro (ame	Use	Comment
	P =0>YES	Are they "EQUAL"? Note: They must be identical. -O does not "equal" +0. Changes nothing!
G	PQQ⊃YES	Is ${\rm Arg}_{\rm p} > {\rm Arg}_{\rm Q}$? Is the argument from P algebraicly greater than that from Q? (Changes D and Z corresponding to q.)
	PLQ>YES	Is ${\rm Arg}_{\rm P}<{\rm Arg}_{\rm Q}$? Is the argument from P algebraicly less than that from Q? (Changes D and Z corresponding to q.)
2	P ?>GR <ls=fq< td=""><td>Three exits, same rules as for YES and NO, (see note 4 above). GR for ${\rm Arg}_{\rm p} > {\rm Arg}_{\rm Q}$ IS for ${\rm Arg}_{\rm p} < {\rm Arg}_{\rm Q}$ and EQ for ${\rm Arg}_{\rm p} = {\rm Arg}_{\rm Q}$. But this time ${\rm O} = -{\rm O}$. (Changes D and Z corresponding to q.)</td></ls=fq<>	Three exits, same rules as for YES and NO, (see note 4 above). GR for ${\rm Arg}_{\rm p} > {\rm Arg}_{\rm Q}$ IS for ${\rm Arg}_{\rm p} < {\rm Arg}_{\rm Q}$ and EQ for ${\rm Arg}_{\rm p} = {\rm Arg}_{\rm Q}$. But this time ${\rm O} = -{\rm O}$. (Changes D and Z corresponding to q.)
H	∏⊃YES	Pointing at a HEN? (Ring Start Tie Register) (No config. "q", no Q) Changes ${\rm A}_{43}$ and $\alpha.$
77	MOYES	Pointing at some kind of NUB? (No config. "q", no Q) Changes ${\rm A}_{43}, \ \alpha,$ and ${\rm Y}$.
B P NBB	IT=J→K⊃YES NO	BIT is the Bit number - in the form 2.7; P N is where to find it, (N is a number up or down from P,) Question is, "Is BIT equal to J?" K is what the bit should be changed to. Hence, the macro reads: $B: t \circ f(P+N) = J? \supset yes/No$, set $B: t \circ K$

Changes α .

TP>YES NO

Pointing at a block of type TP? (Naturally, you wouldn't be pointing at the Data part.) Changes A_{43} , B, C, D, α , γ and clears all overflow flops (Z_1, Z_2, Z_3, Z_4) .

C. Data

Macro Name	Use	Comment
K	[N~ q	This macro turns into a ^{q}LDA (a + N) where "a" is the right half of Acc and N is a number. Changes A via config. q, and α .
	P∏-+S .	What Type of block is this? Changes A, B, C, D, α , γ and clears all overflow flip-flops.
I	P∐→S	What Length block is this?
Ū	PŪ→S	What is the length of the Non Data part of this block?

Note: For the last 3 ($\boxed{1}$, $\boxed{1}$, and \boxed{J}) the following is true:

- a) The answer to the question goes into the right half of Acc.
 - b) The original pointer goes in the right half of B and a pointer to the top of the block goes into the left half of B.

D. A. E. Macros

Name	Use	Comment
<u>+</u>	X <u>+</u> Y~ <i>q</i> →Z	ADD
<u>-</u>	X <u>-</u> Y~ <i>q</i> →Z	SUB
×	X <u>×</u> Y∧N~ <i>q</i> →Z	MUL, then SAB N places
7	X <u>/</u> Y^N∩P→Z	SABN, then DIV, Qustient goes into Z. If overflow, go to P. Remainder is left in B and includes initial B contents not shifted out. If N is left out, B is cleared to + O depending on A.
^	X <u>^</u> Y~ <i>q</i> →Z	Interest (MASK, AND)
<u>~</u>	X <u>∨</u> Y~ <i>q</i> →Z	Unite (inclusive OR)
<u>©</u>	X <u>⊚</u> Y~ <i>q</i> →Z	Distinguish (Partial Add, Exclusive OR)
Τ	X <u> </u> ~ <i>q</i> → Z	Magnitude of x (Absolute Value, Make x Positive)
→	X <u>→</u> Y→Z	Put contents of x in Y and Z.

- Note: 1. X, Y can be what you wish Tag, Macro, configured, Indexed, etc.
 - 2. N must not be a Macro.
 - 3. q is the configuration used on the operation itself. (You can therefore use 3 configurations on X, on Y, and on the operation.) Note that there are no restrictions on q any config. is OK.

E. Misc. Macros

Name Use Comment X PM1 | W2 | W3 | W4->S Do W1, W2, W3, W4. The Macro definition merely lists the parameters as follows: Wl W2 W3 W4 They can therefore be whatever you wish. The macro itself changes nothing. "GO" to result of or contents of Q with contents PFQ of or result of P in right half of Acc. Changes A43. Do 'W" N/Z times using index X . Uses α if X is DO WNZX DO . not given. Z is the index increment. Note: 1. Any W will be whatever you write -- be it subroutine, macro, or what have you. F. Change Macros!

Name	Use	Comment	
⊗	P⊗Q→S	Put P to the right of Q. becomes a HEN.	If Q is nothing, it
			•
0	P⊗Q→S	Put P to the left of Q.	

1	Name '	Use	Comment
(③	P⊕	Take P. Take unties a chicken from its ring, reties the ring, and leaves Acc pointing at the taken chicken (now a nothing.) At the moment, take should not be used on MENS.
0		P@TP^L TIE→S	Make a block of type TP or of same type as block P points at. L is for non-standard Length. "TIE" is used if you wish a tie to the master in the second reg. of block. Acc. is left pointing at the 2nd. register of the block.
C		TP⊜L×LL→S	Block Type TP is defined to have L registers and (LL - 1) Tie Registers.
@)	®T P	Make nub of type TP.
Ф)	хфг	Create Master Master block at X (Stand List Structure of length L.

CLASS MACROS -- For Speed, Economy, Flexibility, and Convenience

X⊕P N~q

- 1. Any Grouping of Data Blocks can be considered a "CLASS".
 - a) The same set of subset of Blocks can be grouped several ways hence forming several CLASSES.

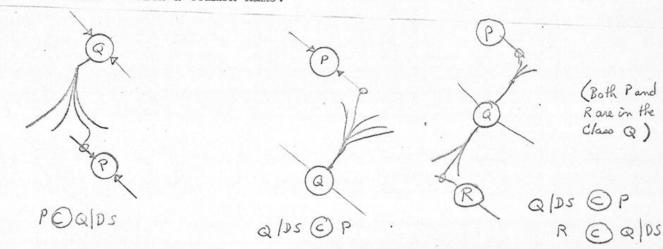

Store datum χ at (P + N) via config. q.

- b) The order of the grouping may depend on the data itself, on the block type number, or on the order of insertion of the blocks.
- c) The grouping is done, of course, by ties -- the blocks exist but once.

- 2. A SUBGROUP is automatically generated when two or more elements have the same ordering criterium. The ordering within the subgroup will be pushdown. (Pushdown can be from either end.)
- 3. There are two macros for insertion of a data block into a CLASS grouping: "PUT FIRST", \odot and "PUT IAST", \odot . (They are analogous to Fut Right \odot and Put left \odot .)
- 4. The "PUT IN CLASS" macros have parameters for specification of the ordering desired. This gives rise to 3 basic versions of the two macros: (illustrated for Put Last.)
 - a.) POQ PUT P LAST IN Q
 - b.) P@Q DS PUT P LAST IN Q ACCORDING TO DS
 - c.) Q DSCP PUT P LAST IN Q ACCORDING TO DS
- 5. There is a difference between cases b and c above. Classes can be given Hierarchial Status. The class on the left of the symbol © is SUBORDINATE to the class on the right.

When DS is used, it is a macro or subroutine that conjures up a 36-bit ordering number - either from the block itself or by charging off to some other place. (Ordering numbers less than 36-bits must be sign extended.)

The logarithmic search structure can be diagrammed as a "TREE". If $P \otimes Q \mid DS$ is used, Q is superior, and the tree branches downward towards P. If $Q \mid DS \otimes P$ is used, P is superior, and the tree branches upward toward P. Note that a block can have two trees - one "up" and one "down" - with a common name.

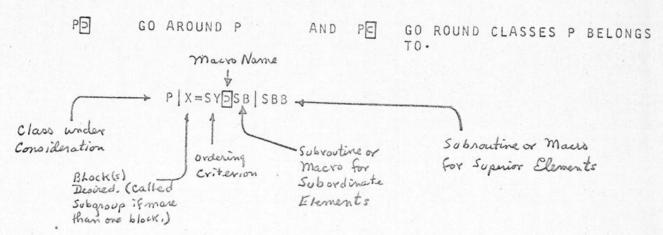

6. The hierarchial structure becomes significant when the Delete Macro
"

" (circled Multiply Sign) is used. Delete in simple form
deletes everything it can get at going downwards. Any block left
"hanging" -- i.e. with nothing pointing to it is also deleted. Delete
takes two forms:

P⊗ DELETE P

P⊗Q DELETE P FROM Q

7. There are two "Go Around" Macros:

Although you can look at superior and subordinate elements separately, they are on the same ring and will be considered in the proper order regardless of their hierarchial status. (You can, of course, use P $P \supseteq SB \mid SB = 1$ if all elements are desired without distinction) The parameters are:

P - The class to be considered

- A 36-bit number, the block desired. If there is more than one, they are considered in the order of generation (First to Last or Vice-Versa depending on Put Macro used)

 If no such element was found, or after the last one, the macro exists to the next line on the manuscript and is pointing to the next higher element.
- SY SY is the ordering criterium. It is repeated here for speed.

 (It could have been remembered by Put, perhaps.)
- SB A subroutine or macro to be done for all subordinate blocks.
- SBB For all Superior blocks.
- "Go Around Classes P belongs to" SB is "done" for subordinate classes, SBB for superior classes (They could be the same, The order is determined by the order of creation. (Each time P became a member of some class, that class went last on the ring of "classes P belongs to".)
